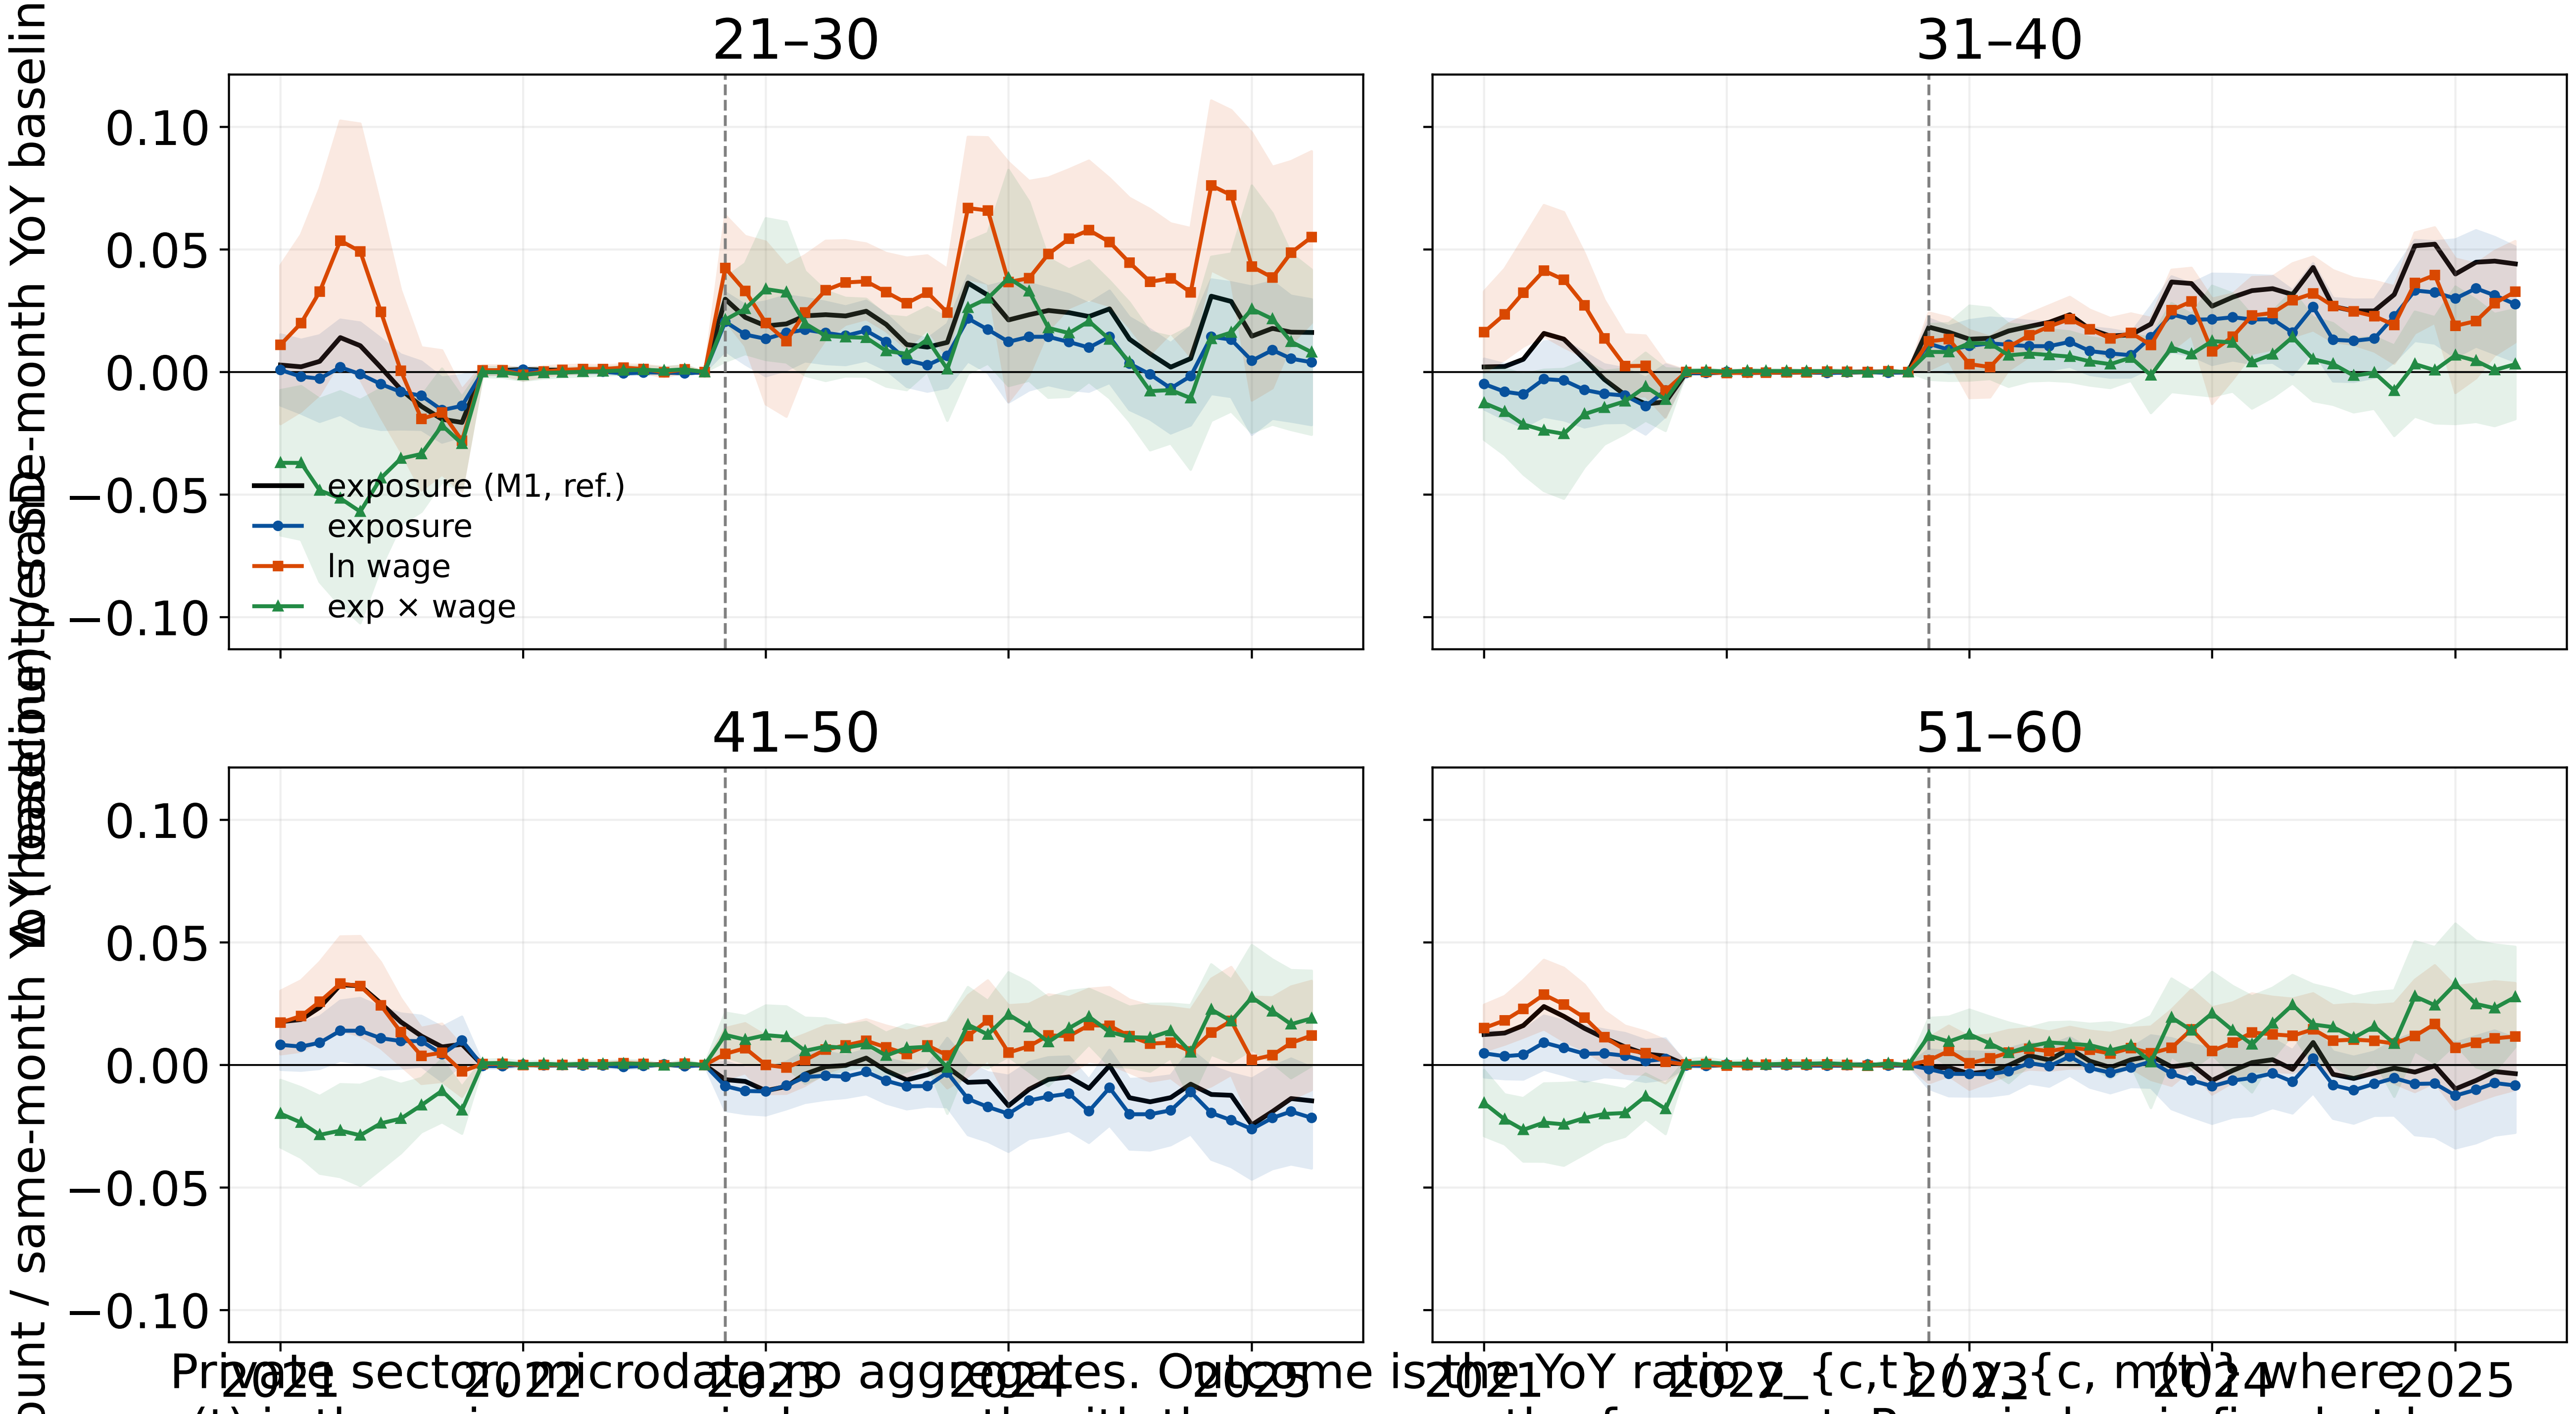
CA event study, all terms (employment headcount); YoY-matched ratio (y / same-month-of-year pre-baseline); re-anchored Oct 2022 = ChatGPT



Private sector microdata, no aggregates. Outcome is the YoY ratio y_{c,t} / y_{c, m(t)} where m(t) is the unique pre-window month with the same month-of-year as t. Pre-window is fixed at k ∈ [−12, −1] per anchor, so the baseline never moves into the post-treatment period. Pre-period y_ratio = 1 by construction. Full model: z(exposure), z(ln FTE wage) and their interaction, each × event-time dummies (k=−1 ref). Linear OLS with occupation + month FE, weighted by pre-window baseline count; 95% CI bands; SE clustered at occupation. Dashed = reference launch.
