

Private sector microdata, not aggregates. Outcome is the YoY ratio $y_{c,t} / y_{2025}(t)$ where 2026 m(t) is the unique pre-window month with the same month-of-year as t. Pre-window is fixed at $k \in [-12, -1]$ per anchor, so the baseline never moves into the post-treatment period. Pre-period $y_{ratio} = 1$ by construction. Full model: $z(\text{exposure})$, $z(\ln \text{ FTE wage})$ and their interaction, each $\times$ event-time dummies ($k=-1$ ref). Linear OLS with occupation + month FE, weighted by pre-window baseline count; 95% CI bands; SE clustered at occupation. Dashed = reference launch.
