

Interaction event study across INT specifications (nyjobb); re-anchored Apr 2025 = agentic

Each line is the interaction term δ_k from a model that also includes the free linear $z(\text{exp})$ and $z(\ln \text{ wage})$ gradients; only the interaction's definition changes. y-axis clipped to ± 0.06 ; the rectified-at-+1SD path is noisy in the youngest group (thin tail support) and runs off-scale pre-period. Private sector, Poisson PPML, occ + month FE; SE clustered at occupation. Model: $z(\text{exp})$, $z(\ln \text{ FTE wage})$ and one interaction term, each $\times$ event-time ($k=-1$ ref). All paths are Δires per 1 SD of the construct. Dashed grey = reference launch.
